

README – Metabolomics of Tibialis Anterior (HO-1/HO-2 KO)

Study Overview

This dataset contains metabolomics measurements from tibialis anterior (TA) muscles of mice with double knockout of HO-1 and HO-2 (HO1/2^{-/-}) compared to heterozygous controls (HO1/2^{+/-}). The study was designed to assess metabolic alterations in skeletal muscle associated with loss of heme oxygenase activity, and whether CO treatment modulates these profiles.

Metabolites were measured using high-resolution mass spectrometry, and results are reported as normalized peak intensities.

Experimental Design

- **Genotypes:**
 - **HO1/2^{+/-} oil:** heterozygous animals (controls).
 - **HO1/2^{-/-} tam:** double knockout animals (tamoxifen-induced).
- **Interventions:**
 - **Oil:** vehicle treatment.
 - **Tam:** tamoxifen induction of knockout.
 - **+ CO:** carbon monoxide treatment in HO1/2^{-/-} mice.
- **Groups:**
 - HO1/2^{+/-} Oil
 - HO1/2^{-/-} Tam
 - HO1/2^{-/-} + CO
- **Endpoints:** Relative abundance of metabolites across pathways including amino acid metabolism, nucleotide metabolism, glycolysis, TCA cycle, lipid metabolism, and redox-related intermediates.
